

# Using a shared repository

In the first exercises, you FORKed a project, made changes, and used the DevOps Services Manual Deploy capability to see your changes. At this point, all your code changes are in your private view. To share these changes, you need to commit the changed files and push them to the repository, using the built in Git support. This makes your changes visible to others.

This also enables you to use the automated Build & Deploy capabilities. DevOps Card 1 has step by step directions to commit and push your changes to the repository, and to enable automatic build and deploy.
